GMO in maize flour

1

Overview

- Expressing Measurement Uncertainty (MU)
- What is the Uncertainty Factor ($^F U$) ? *New Eurachem Leaflet**
- How to calculate the Uncertainty Factor
- Worked examples applying the Uncertainty Factor
  - When analytical determination alone is source of MU
    - e.g. GMO in maize flour
    - other applications include microbiological, contaminants in river water & marine sediments
  - When sampling is dominant source of MU (includes UfS)
    - Requirement for including UfS in MU stated in ISO/IEC 17025:2017
- Using the Uncertainty Factor
  - advantages & overcoming challenges (by comparing $^F U$ and U')
- Conclusions
- *Questions and answers*

* https://www.eurachem.org/index.php/publications/leaflets/uncertainty-factor

US University of Sussex

http://dx.doi.org/10.3390/app10144925

2

Introduction

- Uncertainty of a measurement result (MU)
- MU often as important as measured quantity value itself
  - as it controls decisions made using that result (e.g. regulatory compliance)
- Appropriate expression of MU is crucial
  - especially when traditional, symmetric, expanded U interval is not accurate
- This is when concept of Uncertainty Factor (^FU) is useful
  - provides convenient and realistic uncertainty interval in particular circumstances

US University of Sussex

3

Ways of expressing measurement uncertainty

- Most labs estimate measurement uncertainty (MU)
  - as either expanded uncertainty (U)
  - or relative expanded uncertainty (U')
  - typically with coverage factor (k) of 2 (for ~ 95 % confidence)
- Measurement result expressed as $x \pm U$
  - where x is measurement quantity value, and $\pm$ is 'plus-minus'
- Range of values that contains value of measurand (i.e. true value of analyte concentration) then between x - U and x + U (for ~ 95 % confidence)
- **Example**: measurement result = 50 ± 5 mg kg^{-1}
- value of measurand believed to lie between Lower Confidence Limit (LCL) 45 (50 - 5) and Upper Confidence Limit (UCL) 55 (50 + 5)

  55
  50
  45

- clearly an <u>**symmetric**</u> **confidence interval**
- Approach works well generally, unless
  - Value of MU is high (e.g. relative expanded uncertainty (U') is over 40 %
    - *Can give LCL value below zero*
  - frequency distribution of repeated measurements is positively skewed
    - rather than Gaussian (i.e. Normal)

US University of Sussex
4

Another way of expressing measurement uncertainty

- When $U' > 40\%$ or frequency distribution of repeated measurements is ~ log-normal :-
- Expanded uncertainty factor (^FU) more accurate way to express MU
- Measurement result expressed as

$$x \; ^{x/} \; ^FU$$

  – for $k = 2$, where '$^{x/}$' is called 'times-over'

- In example - with much larger MU expressed as uncertainty factor of $^FU = 2.0$

  Uncertainty interval $50 \; ^{x/} \; 2.0$ mg kg^{-1}

  is from LCL =   25 (i.e. 50/2)

  to   UCL =   100 (50 x 2)

  - clearly an **asymmetric** confidence interval
  - *and can't give a negative LCL*

100

50

25

US University of Sussex

5

How to calculate the Uncertainty Factor

- **Standard uncertainty factor (^Fu)** calculated* as

$$^Fu = \exp(s_G) = e^{s_G}$$

  – where s_G is the standard deviation of the $\log_e$-transformed measurement values (x) *(see Example)*

$$s_G = s(\ln(x)) = s(\log_e(x))$$

- **Expanded uncertainty factor (^FU),** for 95% confidence, calculated as

$$^FU = \exp(2s_G) = e^{2s_G}$$

- **Worked examples**
  1. Analysis only – GMO in Maize Flour – simple 'manual' calculation of ^FU in Excel
  2. Sampling and analysis - Pb-contaminated soil – from Eurachem UfS Guide (2019)
     - ^FU calculated automatically, by applying ANOVA to results of 'duplicate' method

Mean	0.796
SD = sG	0.691
$^F u$ = exp(s_G)	2.00
$^F U$ = exp(2s_G)	3.98

- Single PCR measurements from 31 labs in single PT round in 2004
  - on same test material
- Heavy positive skew
- Log_e transformation required to approach Normal distribution
  - command LN(x) in Excel
- Standard deviation of transformed measurement $s_G = 0.691$

$$^F u = \exp(s_G) = \exp(0.69) = 2.00$$
$$^F U = \exp(2s_G) = \exp(2*0.69)$$
$$^F U = 3.98 = 4$$

GMO in maize flour

GMO in maize flour

7

Interpretation of $^F U$ for **GMO in Maize Flour**

- MU on typical <u>single measurement value</u> of 2 % GMO on this one material

- Measurement result is 2 */ 4 % GMO
- LCL = 2/ 4 = 0.5 %
- UCL = 2*4 = 8 %

- Reflects MU of each PT result overall
- Better match to real distribution here
  - *But not all GMO distributions are approx. log-normal*
- ***No risk of negative LCL***

GMO in maize flour

9

Other published Analytical applications of $^F U$

- Microbial contamination (e.g. of pharmaceutical products)[1]
  - $^F U_{anal} = 1.2 – 3.0$
- Rapid microbiological methods[2]
  - need $^F U$ due to lognormal distribution of potency values
  - $^F U_{anal} = 1.08 – 1.13$
- Contaminants in marine sediments (e.g. 29 polycyclic aromatic hydrocarbons)[3]
  - U' often exceeds 30% and appears log-normally distributed
- Analytical $^F U$ within MU of 25 contaminants in river water[4]
  - $^F U_{anal} = 1.1 – 2.1$ (13 contaminants > 1.4)

^FU Estimation (including UfS) using Duplicate Method & ANOVA

Lab would need to collaborate with Sampling Organisation

Scenario:

- Contaminated land investigation
- Former landfill, in West London
- 9 hectare = 90 000 m^2
- Potential housing development
- measurand → [Pb] in each sampling target

Area of investigation:

- 300 m x 300 m area → depth of 0.15 m
- 100 sampling targets in a regular grid (10 x 10)
- 100 primary samples (taken with soil auger)
  - each intended to represent a 30 m x 30 m target

Example A2 : From Eurachem UfS Guide (2019), http://www.eurachem.org

US University of Sussex

11

Application of Duplicate Method to estimate MU inc. UfS

Figure 1: A balanced design

Sampling target

Sample 1   Sample 2

Analysis 1   Analysis 2   Analysis 1   *Analysis 2*

S1A1   S1A2   S2A1   S2A2

10% of targets in whole survey

→ between-target variance

between-sample variance

between-analysis variance

- Duplicate samples taken at 10/100 sampling targets (i.e. 10%)
  - randomly selected
  - Duplicate sampling point 3 m from the original sampling point
    - within the sampling location
    - in a random direction - within the sampling target

US University of Sussex

12

Application of Duplicate method to estimate UfS

Aims of design of duplicate taking to reflect:-
- ambiguity in the sampling protocol
  - how differently could it be interpreted by a different samplers?
- uncertainty in locating sampling location within sampling target
  - e.g. survey error by using tape and compass
- effect of small-scale heterogeneity within each sampling target on measured concentration
  - e.g. at 10% of grid spacing distance, 3m for 30m

US University of Sussex

13

Sample prep and analysis in the lab

- Soil samples dried, sieved (<2 mm), ground (<100 μm)
- Test portions of 0.25g digested in nitric/perchloric acid
- [Pb] measured with ICP-AES, under full AQC
- 6 soil CRMs measured to estimate analytical bias
  - over range of concentration
  - found to be negligible (- 3%) – *discussed further in UfS Guide (Example A2)*
- corrected for reagent blank concentrations
  - where statistically different to zero
- Raw measurements for use for estimation of uncertainty were:
  - **untruncated** – e.g. 0.0124 mg/kg, <u>not</u> < 0.1 or < detection limit
  - **unrounded** – e.g. 2.64862 mg/kg, <u>not</u> 3 mg/kg

US University of Sussex

14

Duplicated Measurements for MU estimation (including UfS)

Sampling target

Sample 1　　　　　Sample 2

- **Large differences between some sample duplicates** (e.g. D9) = high level of UfS

- Good agreement between **analytical duplicates** (< 10 % difference)

Target #	Analysis 1 S1A1	Analysis 2 S1A2	Analysis 1 S2A1	*Analysis 2* S2A2
A4	787	769	811	780

I9	189	189	176	168
J5	61	61	91	119

mg kg^{-1}

- Needs inspection of frequency distribution to select the best approach to UfS estimation

US University of Sussex

15

Estimating the Uncertainty as ^FU - Histograms

- Frequency distribution of [Pb] <u>across the site</u> = long range heterogeneity
- Distribution of Pb measurements on 100 sampling targets is positively skewed = approximately log-normal
- Log-transformation necessary to remove skew
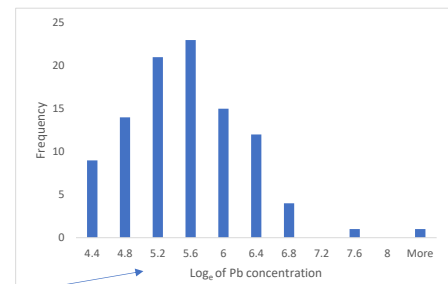

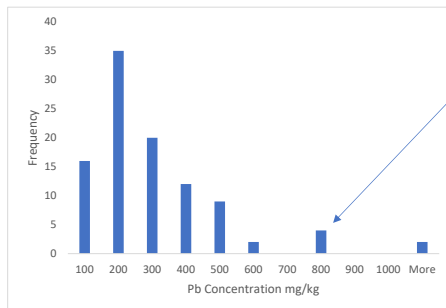

- Distribution closer to Normal after $\log_e$ transformation

US University of Sussex

16

Estimating the Uncertainty as ^FU - Scatter Plots

Frequency distribution of [Pb] <u>between each sample duplicate</u>   = UfS part of MU
     mainly due to within-target (short range) heterogeneity.

Pb concentration values made on duplicated samples (10 of 100 targets) in either:-

(a) original concentration units

Duplicate samples (S1 ⦂ , S2 ⦂) generally differ by more than the duplicate analyses
(A1 and A2 in same colour) - as seen in Table

(a) Four targets (2, 4, 6 and 7) have particularly large difference between duplicate
samples, suggesting a positively skewed distribution for sampling uncertainty,

- like that between the targets (in previous Histogram).

e.g. D9

(b) log$_e$ transformed

Values show generally much smaller differences, more similar across range of
concentration.

Distribution made closer to normal by log transformation (like Histogram #2).

17

Need for log-transformation?

- Classical analysis of variance (ANOVA) assumes approximately normal distributions
- Robust ANOVA can accommodate up to 10% outlying values,
    - but not more, and not heavy skew as in this case
- Use of log-transformation (where there is a log-normal distribution), can:
    1. Avoid negative LCL (lower confidence limit) - clearly impossible,
        i.e. when a normal distribution is assumed erroneously
    2. Compensates for any approximate proportional change of U with increasing concentration
    3. Enables justified use of Classical ANOVA (if log-transform produces a near normal distribution)
- However, transformed measurement values (and ANOVA results) <u>are no longer given in input units</u> of concentration (e.g. mass fraction, mg kg $^{-1}$)

RANOVA2 output for Soil Example

Classical ANOVA

Mean	*317.8*		No. Targets	*10*
Total Sdev	*240.19*			
	Btn Target	Sampling	Analysis	Measure
Standard deviation	*197.55*	*135.43*	*17.99*	*136.62*
% of total variance	*67.65*	*31.79*	*0.56*	*32.35*
Expanded relative uncertainty (95%)		*85.23*	*11.32*	*85.98*
Uncertainty Factor (95%)		*2.6032*	*1.12*	*2.6207*

- Software RANOVA2* (in Excel) performs Classical
- Classical ANOVA output gives poor estimate of **U' = 86%** (due to heavily skewed distribution)
- but also estimate of **^FU as 2.62** (after automatic $\log_e$-transformation)
- Transformation can be either to base 'e' or to base 10
  - Get same ^FU, but $\log_e$ has some advantages, and is recommended
- RANOVA2, does $\log_e$ transformation internally and calculates ^FU directly
  - Also performs Robust ANOVA – not applicable in this case (> 10% outliers)

  - https://www.rsc.org/membership-and-community/connect-with-others/through-interests/divisions/analytical/amc/software/

US University of Sussex

19

Uncertainty Factors of components of MU

Classical ANOVA

Mean	*317.8*		No. Targets	*10*
Total Sdev	*240.19*			
	Btn Target	Sampling	Analysis	Measure
Standard deviation	*197.55*	*135.43*	*17.99*	*136.62*
% of total variance	*67.65*	*31.79*	*0.56*	*32.35*
Expanded relative uncertainty (95%)		*85.23*	*11.32*	*85.98*
Uncertainty Factor (95%)		*2.6032*	*1.12*	*2.6207*

- Classical ANOVA on <u>raw data </u>using 'RANOVA2' gives:

- $^FU_{sampling}$ = 2.60 = expanded uncertainty factor of the **sampling**

- $^FU_{analysis}$ = 1.12 = expanded uncertainty factor of the **analysis** – *really analytical repeatability (U'~12%)*

- $^FU_{meas}$ = 2.62 = expanded uncertainty factor of the **measurement**

US University of Sussex

20

Confidence Limits on Measurement Value

- *For $^F U$ = 2.62, for a typical Pb measurement value of 300 mg kg^{-1}*

  Upper confidence limit (UCL) = 784 mg kg^{-1} (300 x 2.62)

  Measurement value of 300 mg kg^{-1}

  Lower confidence limit (LCL) = 115 mg kg^{-1} (300 / 2.62)

- <u>Asymmetric confidence limits</u> around the measured value
- -185 and +484 mg kg^{-1} (away from 300)
- Reflects skew in frequency distribution of the uncertainty
  as seen in scatter plot & histograms

- Not seen in <u>symmetrical confidence limits</u> from classical $U' = 86\% = 258$ (300 * 0.86)
  = 300 +/- 258 mg kg^{-1}

  UCL = 558 (300 + 258)
  LCL = 42 (300 - 258)

  – calculated without log-transformation
  – doesn't reflect actual (skewed) distribution.

US University of Sussex

21
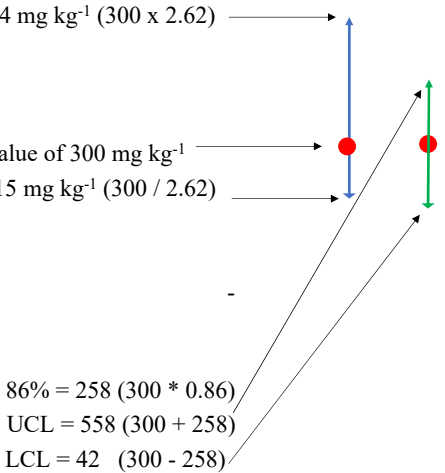

Understanding Uncertainty Factor by comparison with U'

Get appreciation for meaning of $^F U$

From rough approximation. $$U' \approx {}^F U - 1$$

e.g.

**$^F U$ = 1.05 is roughly equivalent to $U' = 5\%$ - really ~4.9%**
$^F U = 1.10$ " $U' = 10\%$ - really ~9.5%
$^F U = 1.15$ " $U' = 15\%$ - really ~14%
$^F U = 1.20$ " $U' = 20\%$ - really ~18%

Predicting U' from $^F U$ - 1

- i.e. 10% overestimate at 1.2 - but a useful rough guide at low levels
- Breaks down at high levels: 20% overestimate at $^F U = 1.50$, really 40%

- Gives instant intuitive appreciation of $^F U$ values

  – Calculations based upon a better approximation $u' = \sqrt{\exp(s_G^2) - 1}$

US University of Sussex

22
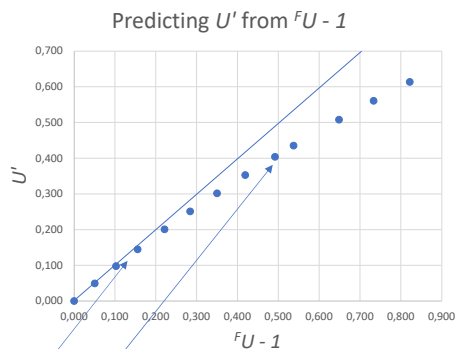

Conclusions

- Uncertainty Factor (^FU) is a useful alternative way to express measurement uncertainty when:
  – Uncertainty values are high ($U' > 40\%$)
  – Frequency distribution (of MU) is visibly log-normal (e.g. highly positively skewed)
- ^FU apply to purely analytical sources, when U' is high (> 40%)
  – e.g. contaminant in water/sediment, microbiology, and some cases of GMO by PCR
  – Where there is an inherent expectation of log-normal distributions (e.g. PCR)
- When sampling materials with substantial heterogeneity of analyte concentration (within or between-target) – for estimation of UfS and MU
- Also allows for possible variation of U, with U proportional to concentration
- Never gives a negative Lower Confidence Limit
- ^FU can give more accurate Confidence Limits (e.g. UCL) for make assessments of compliance
- ^FU is harder to explain, but can made more accessible through Eurachem Leaflet* on ^FU
  – and through approximations e.g. $^FU = 1.20 \sim U'$ of 20%

* https://www.eurachem.org/index.php/publications/leaflets/uncertainty-factor
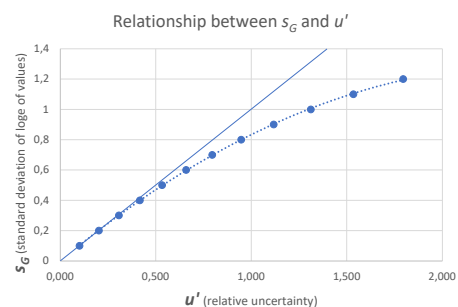

US University of Sussex

23

Relative U & Uncertainty Factor
– advantage of using natural logarithms (not base 10)

- Relative uncertainty u', expressed as a fraction, can be calculated from Approximation*

$$u' = \sqrt{\exp(s_G^2) - 1}$$

- E.g. $s_G = 0.20$, $u' = 0.20$ (=20% RSD)
- Approximation inaccurate if $s_G > 0.5$

Relationship between s_G and u'

s_G (standard deviation of loge of values) — u' (relative uncertainty)

s_G	u'
0	0.000
0.1	0.100
0.2	0.202
0.3	0.307
0.4	0.417
0.5	0.533

* know feature of log-normal distribution, e.g.
